Timer
## 1.0

Features

- 8, 16, 24 or 32-Bit Resolution
- Configurable Capture modes
- 4 deep capture FIFO
- Optional capture edge counter
- Configurable Trigger and Interrupts
- Configurable Hardware/Software Enable
- Continuous or 1 shot run modes

Timer_1

Timer

| capture | tc |
| interrupt |

clock
reset

8-bit(FF)

General Description

The Timer component provides a capture timer used to time the interval between hardware events. The Timer is designed to provide an easy method of timing complex real time events accurately with minimal CPU intervention. The Timer component features may be combined with other analog and digital components to create complex peripherals.

Timers count only in the down direction starting from the period value and require a single clock input. The input clock period is the minimum time interval able to be measured. The maximum timer measurement interval is the input clock period multiplied by the resolution of the timer. The signal to be captured may be routed from an IO pin or from other internal component outputs. Once started, the Timer component operates continuously and reloads the timer period value on reaching the terminal count.

The Timer component capture input is the most useful feature of the timer. On a capture event the current timer count is copied into a storage location. Firmware may read out the capture value at any time without timing restrictions as long as the capture FIFO has room. You should take care to avoid writing to the FIFO if it's full. If the FIFO is full, the oldest value will be over written and the newly captured value returned in its place the next time the FIFO is read. The Capture FIFO allows storage of up to 4 capture values. The capture event may be generated by software, rising edge, falling edge or all edges allowing great measurement flexibility. To further assist in measurement accuracy of fast signals an optional 7-bit counter may be used to only capture every n[2..127] of the configured edge type.

The trigger and reset inputs allow the Timer component to be synchronized with other internal or external hardware. The optional trigger input is configurable so that a rising edge, falling edge or any edge starts the timer counting. A rising edge on the reset input causes the counter to reset its count as if the terminal count was reached.

PRELIMINARY

An interrupt can be programmed to be generated under any combination of the following conditions; when the Timer component reaches the terminal count, when a capture event occurs or after n[1..4] capture events have occurred. The interrupt signal is a read to clear signal.

When to use a Timer

A typical use of the Timer is to record the number of clock cycles between events. A common use is to measure the number of clocks between two rising edges as might be generated by a tachometer sensor. A more complex use is to measure the period and duty cycle of a PWM input. For PWM measurement the Timer component is configured to start on a rising edge, capture the next falling edge and then capture and stop on the next rising edge. An interrupt on the final capture signals the CPU that all the captured values are ready in the FIFO. The Timer component can be used as a clock divider by driving a clock into the clock input and using the terminal count output as the divided clock output.

Timers share many features with counters and PWMs. A Counter component is better used in situations that require the counting of a number of events but also provides rising edge capture input as well as compare output. A PWM component is better used in situations requiring multiple compare outputs with control features like center alignment, output kill and deadband outputs.

Input/Output Connections

This section describes the various input and output connections for the Timer. An asterisk (*) in the list of I/O's states that the I/O may be hidden on the symbol under the conditions listed in the description of that I/O.

clock – Input

The clock input defines the operating frequency of the Timer component. That is, the timer period counter value is decremented on the rising edge of this input while the Timer component is enabled.

reset – Input

Resets the period counter to the period value. Also resets the capture counter. This input is a synchronous reset requiring at least one rising edge of the clock to implement the resets of the counter value and the capture counter.

enable – Input *

Hardware enable of the Timer component. This connection enables the period counter to decrement on each rising edge of the clock. If this input is low the outputs are still active but the Timer component does not change states.

PRELIMINARY

capture – Input *

Captures the period counter value to a 4 sample FIFO in the UDB, or to a single sample register in the Fixed Function Block. The input pin is visible if enabled by the CaptureMode parameter as set in the parameter editor.

trigger Input *

When the TriggerMode parameter is enabled, this input displays to enable the selected period counter value.

tc – Output

Terminal count output goes high if the count value is equal to the terminal count (zero). The terminal count output is a zero compare of the period counter value, as long as the period counter is zero the output will be high.

interrupt – Output

The interrupt output is a copy of the interrupt source configured in the hardware. The sources of the interrupt are configured through software as being any of the status bits:

- Terminal Count Event
- Capture Event
- One to four captures have occurred

Once an interrupt has been triggered, the status register must be read in order to clear it. This is easily done using either Timer_GetInterruptSource() or Timer_ReadStatusRegister().
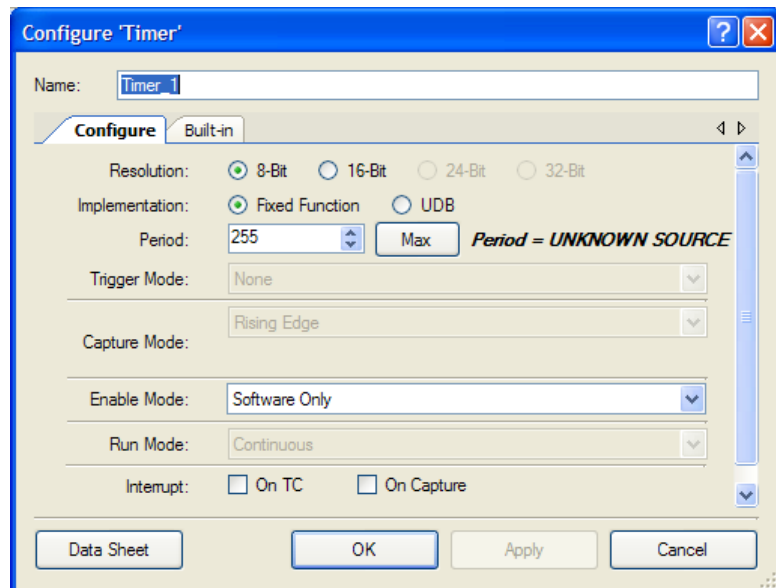

capture_out – Output *

The capture_out output is an indicator of when a hardware capture has been triggered. The output pin is available for the UDB implementation only.

Parameters and Setup

Drag a Timer component onto your design and double-click it to open the Configure dialog.

Figure 1 Configure Timer Dialog

Hardware Configuration Options

Hardware configuration options change the way the project is synthesized and placed in the hardware. You must rebuild the hardware if you make changes to any of these options.

Resolution

The Resolution parameter defines the bit-width resolution of the Timer. The default is 8-bit.

Implementation

The Implementation parameter allows you to choose either a fixed function block (default) or a UDB implementation of the Timer.

CaptureCounterEnabled (bool)

The Capture Counter Enabled parameter allows you to implement a 7-bit counter that is accessible by software to define how many capture events happen before the period counter is captured to the FIFO. It may be necessary to capture every 3rd event in which case the capture counter should be set to a value of 3. If this parameter is set the 7-bit counter may be changed at any time with the API SetCaptureCount().

PRELIMINARY

EnableMode (enum)

Specifies the mode of the component:

- "Software Only": The Timer is enabled only by setting the enable bit in the control register. In this mode the enable input pin will be hidden from the symbol.

- "Hardware Only": The Timer is enabled only by setting the enable bit in the control register. In this mode the control register may be removed from the implementation but the control register enable bit has no affect on operation. This option is only available when Implementation is set to "UDB."

- "Hardware and Software": The Timer is enabled only if both the control register bit and the hardware input are active (high).

RunMode (enum)

The Run Mode parameter allows you to configure the Timer component to run continuously or in one of two one shot modes as defined by the enumerated types available. The "RunMode" enumerated types are defined as follows:

- "Continuous": The Timer will run so long as the enable conditions are true

- "One Shot": The Timer will run through a single period and stop at terminal count until the Timer component period counter is reset or the Timer component is hardware reset at which point it will begin another single cycle

- "One Shot halt on Interrupt": The Timer will run through a single period and stop at terminal count or any interrupt until the Timer component period counter is reset or the Timer component is hardware reset at which point it will begin another single cycle

NumberOfCaptures (uint8)

The number of captures parameter defines the number of captures to count before an interrupt on capture is triggered. This allows software to deal with capture data only after the data expected is available and to not be overworked by calling the ISR too often.

PRELIMINARY

Software Configuration Options

Software configuration options do not affect synthesis or placement. When setting these parameters before build time you are setting their initial value which may be modified at any time with the API provided.

Period

The Period parameter defines the max counts value (or rollover point) for the period counter. The default is 255. The limits of this value are defined by the Resolution parameter. The maximum value of the Period value is defined as $(2^8)-1$, $(2^{16})-1$, $(2^{24})-1$, and $(2^{32})-1$ as shown in the following table. The period value may be modified by the API WritePeriod().

Resolution	Maximum Period Count Values
8	255
16	65535
24	16777215
32	4294967295

CaptureMode (enum)

The Capture Mode parameter configures the implementation of the capture input. This value is an enumerated type - "CaptureMode" - and can be set to any of the following values:

- "None": No capture implemented and the capture input pin is hidden

- "Rising Edge" (default): Capture the period counter value on any rising edge of the capture input

- "Falling Edge": Capture the period counter value on any falling edge of the capture input

- "Either Edge": Capture the period counter value on any edge of the capture input

- "Software Controlled": Control register bits define what edge of the capture input to use to capture data to the FIFO. May be changed at any time by API by setting calling the Timer_SetCaptureMode() function

Capture is available in the fixed function timer implementation but is not configurable to which edge. All capture on the fixed function block is implemented on the rising edge of the capture input.

CaptureAlternatingRise

Not implemented as a software feature. Can only be done at initialization currently and this needs to be fixed.

PRELIMINARY

CaptureAlternatingFall

Not implemented as a software feature. Can only be done at initialization currently and this needs to be fixed.

TriggerMode

The Trigger Mode parameter configures the implementation of the trigger input. This value is an enumerated type - "TriggerMode" - and can be set to any of the following values:

- "None" (default): No trigger implemented and the trigger input pin is hidden

- "Rising Edge": Trigger (enable) the period counter value on the first rising edge of the trigger input

- "Falling Edge": Trigger (enable) the period counter value on the first falling edge of the trigger input

- "Either Edge": Trigger (enable) the period counter value on the first edge of the trigger input

- "Software Controlled": Control register bits define what edge of the trigger input to use to trigger the timer. May be changed at any time by API by setting calling the Timer_SetTriggerMode() function

The trigger mode is not available in the fixed function timer implementation. Therefore the configuration window does not allow the user to set the trigger mode while Fixed Function implementation is selected.

Capture Count

The capture count parameter configures the initial value in the capture counter. The capture counter allows for 2-127 capture events to happen before the period counter value is captured to the data FIFO. If the capture count is set to 100 then every 100th capture event will capture the period counter to the FIFO. The capture count value may be modified by the API SetCaptureCount().

InterruptOnCapture (bool)

The Interrupt on Capture parameter allows you to configure a valid capture as an interrupt source. This value is OR'd with any of the other "Interrupt On" parameters to give a final group of events that can trigger an interrupt. This configures the startup setting, it may be modified at any time with the API SetInterruptMode().

InterruptOnCaptureCount (bool)

The Interrupt on capture count parameter allows you to count a number of captures before triggering an interrupt. This value can be set to a value from 1 to 4 by setting the "NumberOfCaptures" parameter [this may also be set at any time with the API SetInterruptCount()]. This value is OR'd with any of the other "Interrupt On" parameters to give a

PRELIMINARY

final group of events that can trigger an interrupt. This configures the startup setting, it may be modified at any time with the API SetInterruptMode().

InterruptOnTC (bool)

The Interrupt on TC parameter allows you to interrupt on a terminal count. This value is OR'd with any of the other "Interrupt On" parameters to give a final group of events that can trigger an interrupt. This configures the startup setting, it may be modified at any time with the API SetInterruptMode().

Clock Selection

For the Timer component, the clock input can be any signal for which you wish to count the rising edges. It is expected that this input is periodic with its frequency, in combination with the period counts definition of your timer, defining the output period of your timer.

Placement

The Timer component is placed based on the FixedFunction parameter. Whether you set this option or it is set by the auto placement operation, if the FixedFunction is set then this component will be placed in an available fixed function Counter/Timer block; otherwise it will be placed in the UDB array as determined for best placement for the whole design.

PRELIMINARY

Application Programming Interface

Application Programming Interface (API) routines allow you to configure the component using software. The following table lists and describes the interface to each function. The subsequent sections cover each function in more detail.

By default, PSoC Creator assigns the instance name "Timer_1" to the first instance of a component in a given design. You can rename it to any unique value that follows the syntactic rules for identifiers. The instance name becomes the prefix of every global function name, variable, and constant symbol. For readability, the instance name used in the following table is "Timer".

Function	Description
Timer_Start	Enable the Timer for operation; Sets the enable bit of the control register for either of the software controlled enable modes.
Timer_Stop	Disable the Timer operation; Clears the enable bit of the control register for either of the software controlled enable modes.
Timer_SetInterruptMode	Enables or disables the sources of the interrupt output from the optional interrupt sources defined by the bits in the status register.
Timer_GetInterruptSource	Provides an interface where the firmware can query for the source of the a triggered interrupt placed on the interrupt output pin of the Timer
Timer_SetCaptureMode	Sets the capture mode of the Timer from one of the enumerated type options available
Timer_SetTriggerMode	Sets the trigger mode of the timers trigger input from one of the enumerated type options available
Timer_EnableTrigger	Enables the trigger mode of the timer by setting the correct bit in the control register
Timer_DisableTrigger	Disables the trigger mode of the timer by clearing the correct bit in the control regiser
Timer_SetInterruptCount	Sets the number of captures to count before an interrupt is triggered for the InterruptOnCapture source. Only available in a UDB implementation.
Timer_SetCaptureCount	Sets the number of captures events to count before actually capturing the Timer value to the FIFO. Only applicable in the UDB implementation.
Timer_ReadCaptureCount	Reads the current value of the NumberOfCaptures definition which defines the number of captures counted before an interrupt is triggered for the InterruptOnCapture source
Timer_SoftwareCapture	Forces a capture of the period counter to the capture register
Timer_ReadStatusRegister	Reads the status register and returns its state. This function should use defined types for the bit-field information as the bits in this register may be permutable.
Timer_ReadControlRegister	Reads the control register and returns its state. This function should use defined types for the bit-field information as the bits in this register may be permutable.
Timer_WriteControlRegister	Sets the bit-field of the control register. This function should use defined types for the bit-field information as the bits in this register may be permutable.
Timer_ReadPeriod	Reads the Period register returning the last period value written to it
Timer_WritePeriod	Writes the Period register with the new desired period or max counts value

PRELIMINARY

Function	Description
Timer_ReadCounter	Reads the period counter value directly from the Timer. The Timer must not be running when this API is called.
Timer_WriteCounter	Could allow the user to overwrite the counter value as a new location to count down from but I'm not sure what good this would do?
Timer_ReadCapture	Reads the latest captured period counter value. Firmware must check the FIFO status for data before reading
Timer_ClearFIFO	Clears all previous capture data from the capture FIFO

void Timer_Start (void)

Description:	Enable the Timer for operation; Sets the enable bit of the control register for either of the software controlled enable modes.
Parameters:	None
Return Value:	None
Side Effects:	Sets the enable bit in the control register of the counter.

void Timer_Stop (void)

Description:	Disable the Timer operation; Clears the enable bit of the control register for either of the software controlled enable modes.
Parameters:	None
Return Value:	None
Side Effects:	Clears the enable bit in the control register of the counter.

void Timer_SetInterruptMode (uint8)

Description:	Enables or disables the sources of the interrupt output from the optional interrupt sources defined by the bits in the status register.
Parameters:	uint8: interruptsource – Bit-Field containing the status bits you want enabled is interrupt sources. This parameter should be an ORing of the desired status bit masks defined in the Timer.h header file.
Return Value:	None
Side Effects:	All interrupt sources are OR'd together to provide a single interrupt output. You must call Timer_GetInterruptSource to review which enabled status bit caused the interrupt and to clear the interrupt as they are sticky bits in the status register.

PRELIMINARY

uint8 Timer_GetInterruptSource (void)

Description:	Returns the mode register defining which events are enabled as interrupt sources.
Parameters:	None
Return Value:	uint8: Bit-Field containing the enabled interrupt sources as defined by the status register bit-field constants defined in the Timer.h header file
Side Effects:	Clears any active interrupts.

void Timer_SetCaptureMode (enum)

Description:	Sets the capture mode of the timer from one of the enumerated type options available.
Parameters:	enum: capturemode – This parameter should be defined using one of the capture mode constants defined in the Timer.h header file
Return Value:	None
Side Effects:	None

void Timer_SetTriggerMode (enum)

Description:	Sets the trigger mode of the timer from one of the enumerated type options available.
Parameters:	enum: triggermode – This parameter should be defined using one of the trigger mode constants defined in the Timer.h header file
Return Value:	None
Side Effects:	None

PRELIMINARY

void Timer_EnableTrigger (void)

Description:	Enables the trigger mode of the timer by setting the correct bit in the control register
Parameters:	None
Return Value:	None
Side Effects:	None

void Timer_DisableTrigger (void)

Description:	Disables the trigger mode of the timer by clearing the correct bit in the control register
Parameters:	None
Return Value:	None
Side Effects:	None

void Timer_SetInterruptCount (uint8)

Description:	Sets the number of captures to count before and interrupt is triggered for the InterruptOnCapture source.
Parameters:	uint8: interruptcount – The desired number of capture events to count before the interrupt is on capture event is triggered to the interrupt output
Return Value:	None
Side Effects:	None

void Timer_SetCaptureCount (uint8)

Description:	Sets the number of capture events to count before a capture is actually performed. This function is only available if the Capture Counter is enabled with the EnableCaptureCounter parameter.
Parameters:	uint8: capturecount – The desired number of capture events to count before capturing the counter value to the capture FIFO
Return Value:	None
Side Effects:	None

PRELIMINARY

uint8 Timer_ReadCaptureCount (void)

Description:	Reads the current value set for the NumberOfCaptures parameter as set in the SetCaptureCount function. This function is only available if the Capture Counter is enabled with the EnableCaptureCounter parameter.
Parameters:	None
Return Value:	uint8: current capture count
Side Effects:	None

void Timer_SoftwareCapture (void)

Description:	Forces a software capture of the period counter value to the FIFO
Parameters:	None
Return Value:	none:
Side Effects:	Pushes another value onto the capture FIFO

uint8 Timer_ReadStatusRegister (void)

Description:	Returns the current state of the status register
Parameters:	None
Return Value:	uint8: Current status register value – The bit-field constants defined in Timer.h header file match the bits read by this command
Side Effects:	Interrupt bits in the status register are clear on read.

uint8 Timer_ReadControlRegister (void)

Description:	Returns the current state of the control register
Parameters:	None
Return Value:	uint8: Current control register value -The bit-field constants defined in Timer.h header file match the bits read by this command
Side Effects:	None

PRELIMINARY

void Timer_WriteControlRegister (uint8)

Description:	Sets the bit-field of the control register
Parameters:	uint8: Control register Bit-Field. This parameter should be an OR'd grouping of the control register constants defined in the Timer.h header file
Return Value:	None
Side Effects:	None

uint8/16/32 Timer_ReadPeriod (void)

Description:	Reads the Period register returning the last period value written to it.
Parameters:	None
Return Value:	uint8/16/32: Period Value
Side Effects:	None

void Timer_WritePeriod (uint8/16/32)

Description:	Writes the Period register with the new desired period or max counts value.
Parameters:	uint8/16/32: New Period Value
Return Value:	None
Side Effects:	This period value will not be implemented until the current Timer period is complete (i.e. at TC). When TC is reached the new period value will be loaded into the counter and the new period time will take affect until the period value is written over.

uint8/16/32 Timer_ReadCounter (void)

Description:	Reads the latest current period counter value. This API should not be called unless the timer is disabled and not running.
Parameters:	None
Return Value:	uint8/16/32: Counter Value
Side Effects:	Read counter implements a software capture and then a read of the capture register. If there was data already in the capture FIFO before this function is called then that data will be returned and the software capture value will be added to the FIFO and may be read later with a Timer_ReadCapture call

PRELIMINARY

void Timer_WriteCounter (uint8/16/32)

Description:	Writes a value to the counter enabling the user to restart the counter from any value they deem necessary.
Parameters:	uint8/16/32: New Counter Value
Return Value:	None
Side Effects:	None

uint8/16/32 Timer_ReadCapture (void)

Description:	Reads the latest captured period counter value. If no value has been captured to the FIFO then this value will be the current period counter value.
Parameters:	None
Return Value:	uint8/16/32: Counter or Capture Value
Side Effects:	None

void Timer_ClearFIFO (void)

Description:	Clears all capture data from the capture FIFO.
Parameters:	None
Return Value:	None
Side Effects:	None

Sample Firmware Source Code

The following is a C language example demonstrating the basic functionality of the Timer component. This example assumes the component has been placed in a design with the default name "Timer_1."

Note If you rename your component you must also edit the example code as appropriate to match the component name you specify.

```
#include <device.h>
#include "Timer_1.h"

void main()
{
    Timer_1_Start();
}
```

PRELIMINARY

Functional Description

As described previously the Timer component can be configured for multiple uses. This section will describe those configurations in more detail. Before digging into the possible configurations it is important to know the limitations of using the fixed function timer versus the UDB implementation.

Fixed Function Block Limitations

The Counter, Timer, and PWM components have very similar internal requirements that are implemented as fixed function blocks in the chip. There are a few configuration options for one of these blocks, and the limitations of this block as a timer versus the UDB implementation are listed below. The fixed function timer:

- Is 8 or 16-bits only

- Interrupts on Terminal Count and/or Capture only.

- Captures on Rising Edge only.

- Must be run in continuous mode; As a corollary, no trigger mode is available.

- Disables the 7-bit Capture Counter.

- Has a single sample register instead of a 4 sample FIFO for captured values.

Default Configuration

The default configuration of the Timer component provides the most basic timer which simply decrements a period count value on every rising edge of the clock input. With this configuration the component symbol will look like this:

Figure 2: Default Timer Configuration
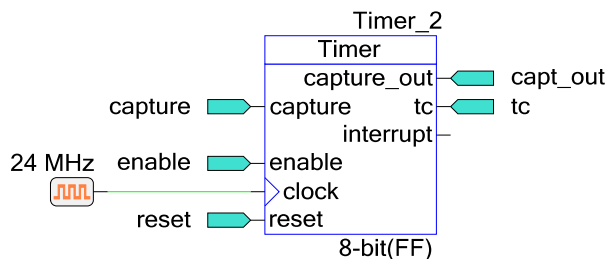

Terminal count indicates in real time whether the counter value is at the terminal count (zero). The period is programmable to be any value from 1 to (2 ^ Resolution) -1.

By default the capture functionality is configured to capture on every rising edge of the capture input.

PRELIMINARY

The capture_out output is an indicator of when a capture has been triggered. It is possible to have multiple capture events on the input before the data is actually captured into the FIFO the output signal allows you to connect any hardware that must be handled on the actual capture event.

The following is a waveform showing the expected results.

Figure 3: Default Timer Implementation Example Waveform
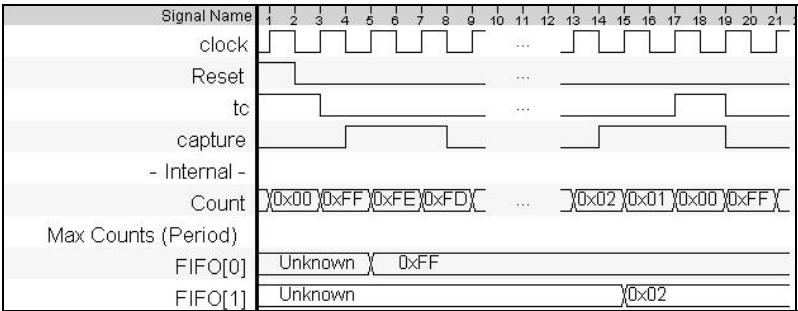

Fixed Function Configuration

When configured to use the Fixed Function block for the Timer implementation, the Timer component is limited in placement options to one of the Fixed Function blocks on the chip. You should consider your resource needs when choosing to implement the Timer component in the fixed function block as an 8-bit timer placed in the Fixed Function block wastes half of the fixed function block.

Block Diagram and Configuration

The Timer component may be implemented using a fixed function block or using UDB components. An advance parameter "Implementation" (FixedFunction) allows you to specify the block that you expect this component to be placed in or you may choose the Auto implementation which will select either of these implementations at build time based on the components and parameters of your entire design. The Fixed function implementation will consume one of the Timer/Counter/PWM blocks defined in the TRM. In either the fixed function or UDB configuration all of the registers and API are consolidated to give a single entity look and feel. The API is described above and the registers are described here to define the overall implementation of the Timer.

The two hardware implementations you chose are selected from a top level schematic as shown below:
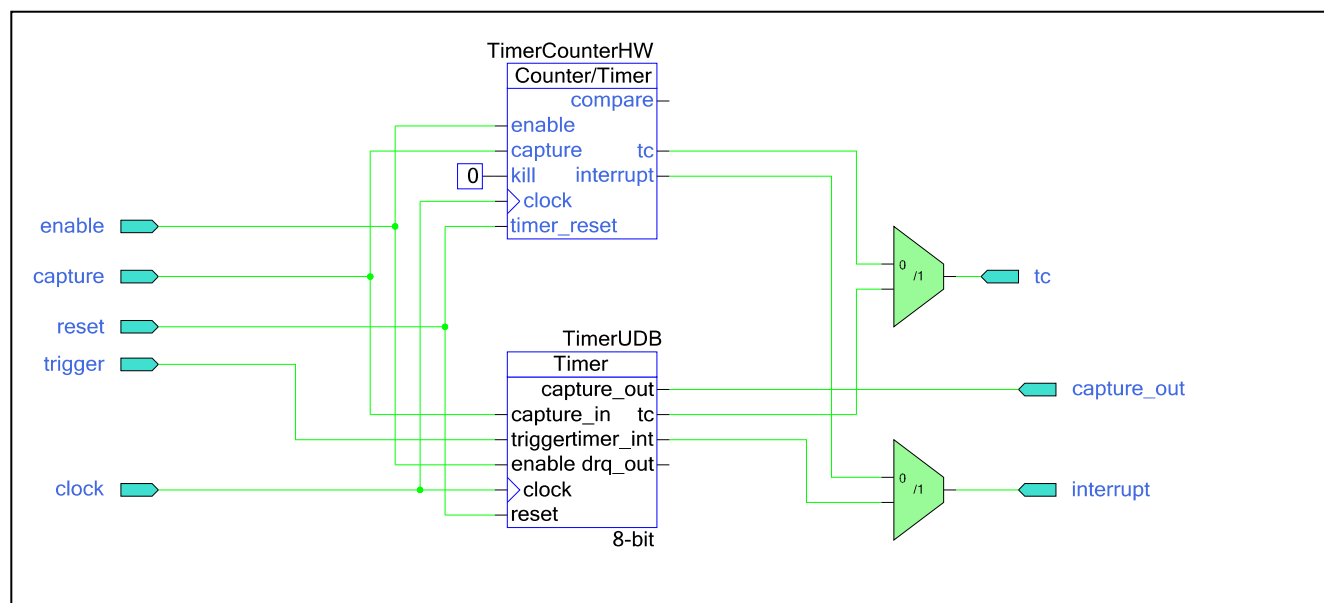

This configuration allows for either the Fixed Function block or the UDB implementation to be selected and the extra pieces such as the internal interrupt and the routing of the I/O are handled in the background to give this single component look and feel.

Registers

Timer_Status

The status register is a read only register which contains the various status bits defined for the Timer component. The value of this register is available with the Timer_ReadStatus() function call. The interrupt output signal (interrupt) is generated from an OR'ing of the masked bit-fields within this register. You can set the mask using the Timer_SetInterruptMode() function call and upon receiving an interrupt you can retrieve the interrupt source by reading the Status register with the Timer_GetInterruptSource() function call. The Status register is a clear on read register so the interrupt source is held until the Timer_GetInterruptSource() or the Timer_ReadStatus() function is called. The Timer_GetInterruptSource() API will handle which interrupts are enabled to provide an accurate report of what the actual source of the interrupt was. All operations on the status register must use the following defines for the bit-fields as these bit-fields may be moved around within the status register during place and route.

There are several bit-fields masks defined in the status register. Any of these bit-fields may be included as an interrupt source. The #defines are available in the generated header file (.h) as follows:

Timer_STATUS_TC

Indicates a terminal count has been reached.

Timer_STATUS_CAPTURE

Indicates a Capture event has been triggered.

Timer_STATUS_FIFO_FULL

Indicates that the capture FIFO is full

Timer_STATUS_FIFO_NEMPTY

Indicates that the capture FIFO is not empty

Timer_Control

The Control register allows you to control the general operation of the counter. This register is written with the Timer_WriteControl() function call and read with the Timer_ReadControl(). When reading or writing the control register you must use the bit-field definitions as defined in the header (.h) file. The #defines for the control register are as follows:

Timer_CTRL_INTCNT

The interrupt count control is a 3-bit bit-field allowing you to configure the number of captures to count before an interrupt is triggered. The value of this bit-field defines a value of 1-4 (as 0-3 + 1) for the number of capture events to count. You can set this value by calling the Timer_SetInterruptCount() function with a value of 0-3.

Timer_CTRL_TRIGPOL

The trigger polarity mode control is a 2-bit field used to define the expected trigger input operation. This bit-field will be 2 consecutive bits in the control register and all operations on this bit-field must use the #defines associated with the capture types available. These are:

      Timer__B_TIMER__TM_NONE

      Timer__B_TIMER__TM_RISINGEDGE

      Timer __B_TIMER__TM_FALLINGEDGE

      Timer __B_TIMER__TM_EITHEREDGE

This bit-field is configured at initialization with the trigger type defined in the TriggerMode parameter. Or this functionality can be set with the Timer_SetTriggerMode() function passing one of the enumerated values listed above. There is no trigger function in the Fixed Function block.

Timer_CTRL_TRIG_EN

The trigger enable control allows you to disable the trigger functionality through software for any period of time when that functionality is not required. While this bit is zero the Timer component will function normally. If this bit set to zero while the timer is waiting for a trigger event the Timer component will resume operation as if a trigger has happened.

Timer_CTRL_CPOL

PRELIMINARY

The capture polarity mode control is a 2-bit field used to define the expected capture input operation. This bit-field is 2 consecutive bits in the control register and all operations on this bit-field must use the #defines associated with the capture types available. These are:

Timer__B_TIMER__CM_NONE

Timer__B_TIMER__CM_RISING

Timer__B_TIMER__CM_FALLING

Timer__B_TIMER__CM_EITHER

Timer__B_TIMER__CM_ALT_RISING

Timer__B_TIMER__CM_ALT_FALLING

This bit-field is configured at initialization with the capture type defined in the CaptureMode parameter.

Timer_CTRL_ENABLE

The enable bit controls software enabling of the Timer component operation. The Timer component has a configurable enable mode defined at build time. If the Enable mode parameter is set to "Input Only" then the functionality of this bit is none. However in either of the other modes the Timer component does not decrement if this bit is not set to one. Normal operation requires that this bit is set and held at one during all operation of the Timer component.

Capture (8, 16, 24 or 32-bit based on Resolution)

The capture register contains the FIFO's capture counter value. Any hardware capture event will push the current counter value onto this FIFO. The FIFO is read one entry at a time using the Timer _ReadCounter() function call. It may be useful to read the status register for the level indication of the FIFO before trying to read from the FIFO. This information is indicated in the STATUS_FIFOFULL and STATUS_FIFONEMPTY status bits.

Period (8, 16, 24 or 32-bit based on Resolution)

The period register contains the period value set by the user through the Timer_WritePeriod() function call and defined by the Period parameter at initialization. The Period register has no affect on the Timer component until a terminal count is reached at which time the period counter register is reloaded.

PRELIMINARY

Counter (8, 16, 24 or 32-bit based on Resolution)

The counter register contains the period counter value throughout the operation of the Timer component. Any hardware capture event will push the current counter value onto the FIFO. This counter is decremented on each rising edge of the clock input so long as the Timer component is in an enabled state.

The counter register should not be written to from the CPU.

Conditional Compilation Information

The counter API requires two conditional compile definitions to handle the multiple configurations it must support. It is required that the API conditionally compile on the Resolution chosen and the Implementation chosen from either the fixed function block or the UDB blocks. The two conditions defined are based on the parameters FixedFunction and Resolution. The API should never use these parameters directly but should use the two defines listed below.

Timer_DataWidth

The datawidth define is assigned to the Resolution value at build time. It is used throughout the API to compile in the correct data width types for the API functions relying on this information.

Timer_UsingFixedFunction

The Using Fixed Function define is used mostly in the header file to make the correct register assignments as the registers provided in the fixed function block are different than those used when the Timer component is implemented in UDB's. In some cases this define is also used with the DataWidth define because the Fixed Function block is limited to 16 bit's maximum data width.

Constants

There are several constants defined for the status and control registers as well as some of the enumerated types. Most of these are described above for the Control and Status Register. However there are more constants needed in the header file to make all of this happen. Each of the register definitions requires either a pointer into the register data or a register address. Because of multiple Endianness` of the compilers, it is required that the CY_GET_REGX and CY_SET_REGX macros are used for register accesses greater than 8-bits. These macros require the use of the _PTR definition for each of the registers.

It is also required that the control and status register bits be allowed to be placed and routed by the fitter engine in that we must have constants that define the placement of the bits. For each of the status and control register bits there is an associated _SHIFT value which defines the bit's offset within the register. These are used in the header file to define the final bit mask as an _MASK definition (The _MASK extension is only added to bit-fields greater than a single bit, all single bit values drop the _MASK extension).

PRELIMINARY

The fixed function block has some limitations compared to the UDB implementations because it is designed with limited configurability. The UDB implementation is implemented according to the following block diagram.

Figure 4 UDB Implementation
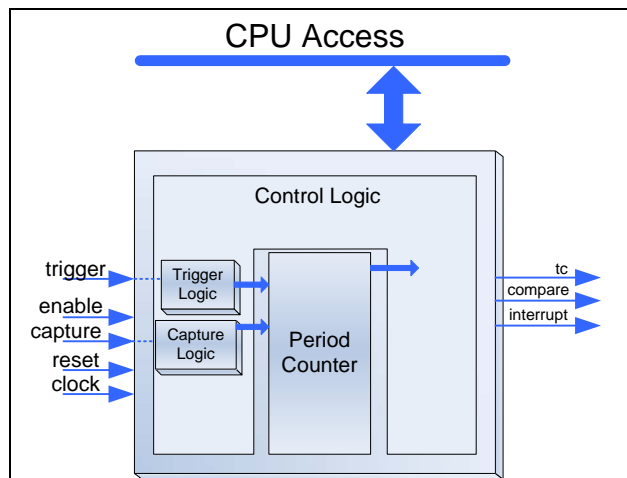

The block diagram above shows the Timer component period counter implemented as a datapath and some control logic. There is a status register and a control register that feed into and come out of the logic cloud as well. All of the logic for the Timer component is the same whether the datapath is 8, 16, 24, or 32-bits wide.
